Ground

Create plane in Unity.

Create a Shader material "Ground" by right clicking on the shader - create - material.

This material from the "Ground" shader can be folded modified depending on the tessellation value.

In the Material there is a box to place the main texture of the "Ground" plane, the texture of the hole "DownGround" and the texture of the elevation that the hole will cause in its border "UpGround".

Create two render textures that will be placed in the material one Down and the other UP, for the hole and for the elevation.

In the plane with the right button create three cameras, one camera down one camera up and another temporary camera.

In Camera UP and Camera Down, leave the rotation on the X axis -90, leave the projection of the cameras in orthographic and put the size and measurements in the same size and height and width of the terrain.

The temporary camera does not need to be configured as it will take the Up and Down camera settings.

On the Down camera and UP camera, place the PostEffect script for the objects seen by the camera to be highlighted and add the DrawSimple shader and CameraTemp to the script.

In CameraUp inside the Post Effect script in Post_Outline add the PostOutlineUp shader.

In CameraDown inside the Post Effect script in Post_Outline add the PostOutlineDown shader.

In both cameras add the CameraTemp in Temp Cam.

To increase the scale of the terrain, increase the view of the camera size, Near and Far.

Before

After

Add objects to the scene.

Removing the AudioSource component from both cameras and turn on Allow HDR on all cameras.

Add Rigidbody to objects.

Changing the values of the UpDisplacement and DownDisplacement to the size of the hole and the elevation is changed.

The higher the value of the Up and Down Displacement, the greater the height of the elevation and depreciation in the plane.

The snow surface is also created with sand but we added the Snow Fall script to recover the snow over time.

Add the Shader GroundFall within the script and the higher the amount and capacity values, the faster the snow is recovered.

Increase DownDisplacement so that the trail is bigger in the snow.

Draw Sand

Add the script Draw with the mouse on the plane with the material of the GroundShader, place the main camera and the DownDraw and UpDraw shaders in the script and change the brush sizes and strength to taste.

Do not put RenderTexture in UpSplatMap and DownSplatMap the script will create render textures and add them to the shader material.
